        %matplotlib inline
        from parametres import VPs, volume, p, d_x, d_y, d_z, calibration, DEBUG
In [4]: from modele_dynamique import arcdistance, orientation, xyz2azel, rae2xyz
        DEBUG parametres , position croix:
        print xyz2azel.__doc__
            renvoie le vecteur de coordonnées perceptuelles en fonction des
       coordonnées physiques
            xyz = 3 \times N \times ...
            Le vecteur OV désigne le centre des coordonnées sphériques,
            - O est la référence des coordonnées cartésiennes et
            - V les coordonnées cartesiennes du centre (typiquement du
       videoprojecteur).
            cf. https://en.wikipedia.org/wiki/Spherical_coordinates
```

## 1 Testing spherical coordinates

```
Plotting function:
```

```
ax.plot(motion[j_ax, :, :], t)
                       elif axe_perc == 'rec':
                           ax.plot(motion_rec[j_ax, :, :], t)
                           if axe_perc in ['az', 'el']: scale = 180./np.pi
                           else: scale = 1.
                       #print motion_x[j_ax, :, :].shape, rae_VC[i_ax-1, :, :].shape
ax.plot(motion[j_ax, :, :], rae_VC[i_ax-1, :, :]*scale)
ax.plot([vp[axe_xyz]], [0.], 'D')
                       ax.set_xlabel(axe_xyz)
                       ax.set_ylabel(axe_perc)
              plt.show()
              return rae_VC
         print plot_xyz2azel.__doc__
              Let's define a function that displays for a particular motion
              (a collection of poistions in the x, y, z space --- usually
              continuous) the resulting spherical coordinates (wrt to vp).
         vp = VPs[1]
In [22]: print vp
         {'cz': 1.36, 'cy': 4.0, 'cx': 11.057115384615384, 'pc_min': 0.001,
         'address': '10.42.0.52', 'y': 4.0, 'x': 0.9428846153846154, 'pc_max':
         1000000.0, 'z': 1.36, 'foc': 21.802535306060136}
Pointing ahead:
         print xyz2azel(np.array([vp['cx'], vp['cy'], vp['cz']]), np.array([vp['x'], vp['y'], v
In [24]: [ 10.11423077
                            0.
                                           0.
Pointing left (bigger y) should give positive azimuth, zero elevation:
         print xyz2azel(np.array([vp['cx'], vp['cy']+1, vp['cz']]), np.array([vp['x'], vp['y'],
In [28]: [ 10.16354584
                            0.0985503
                                           0.
Pointing up (bigger z) should give positive elevation, zero azimuth:
         print xyz2azel(np.array([vp['cx'], vp['cy'], vp['cz']+1]), np.array([vp['x'], vp['y'],
In [29]: [ 10.16354584
                                           0.098550291
                            0
```

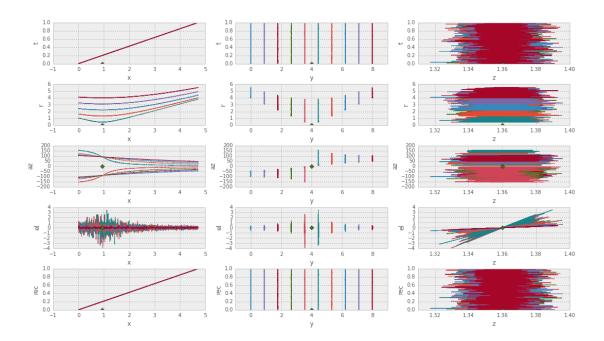

if axe\_perc == 't':

#ax.plot(t, rae\_VC[i\_ax, :, :])

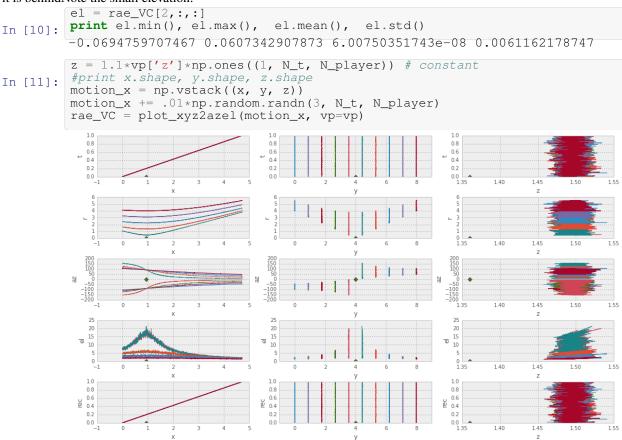

#print motion\_x[j\_ax, :, :].shape, t.shape

### 1.1 Motion in depth

Let's define  $N_p$  layer trajectories of  $N_t$  points, where players are distributed in the width (y) and move in the axis of the VP(x):

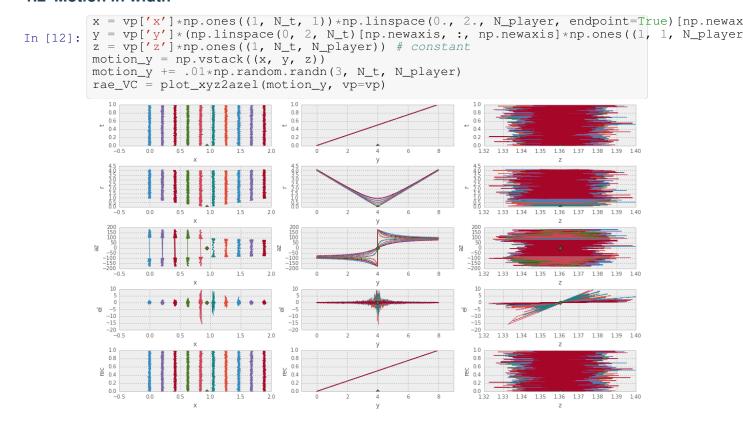

the same but with a motion slightly higer than the VPnote: when azimuth is superior to  $90^{\circ}$  in absolute value, it means it is behindNote the small elevation:

being slightly up creates a small elevation, especially for a trajectory approaching the VP

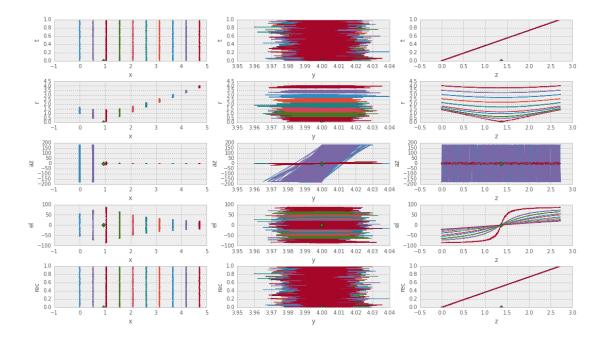

#### 1.2 Motion in width

note that when the motion is behind the observer (x < VP[x]), the azimuth flips from -180° to 180°, everything is normal...

#### 1.3 Motion in height

```
In [13]: x = vp['x']*np.ones((1, N_t, 1))*np.linspace(0, 5., N_player, endpoint=True)[np.newaxi
y = vp['y']*np.ones((1, N_t, N_player)) # constant
z = vp['z']*(np.linspace(0, 2., N_t)[np.newaxis, :, np.newaxis]*np.ones((1, 1, N_player))
motion_z = np.vstack((x, y, z))
motion_z += .01*np.random.randn(3, N_t, N_player)
rae_VC = plot_xyz2azel(motion_z, vp=vp)
```

## 2 Testing great circle navigation

```
Similar tests, but now looking at the arcdistance and orientation functions:
         print arcdistance.__doc__
In [14]:
             renvoie l'angle sur le grand cercle (en radians)
              # rae1 ---> rae2
              r = distance depuis le centre des coordonnées sphériques (mètres)
                    azimuth = declinaison = longitude (radians)
                   elevation = ascension droite = lattitude (radians)
             http://en.wikipedia.org/wiki/Great-circle_distance
             http://en.wikipedia.org/wiki/Vincenty%27s_formulae
         print orientation.__doc__
In [15]:
             renvoie le cap suivant le grand cercle (en radians)
              r = distance depuis le centre des coordonnées sphériques (mètres)
                    azimuth = declinaison = longitude (radians)
              e = elevation = ascension droite = lattitude (radians)
